

实验报告

学生姓名：	汤承洲	学 号：	20233902058
专 业：	电子信息工程	年级、班级：	23 级 2 班
课程名称：	控制工程	实验项目：	控制系统古典分析
实验类型：	☒ 验证 ☐ 设计 ☐ 综合	实验时间：	2026 年 5 月 26 日
实验指导老师：	熊爱民	实验评分：	

1. 实验目的

以 MATLAB 为工具，对控制系统进行时域与频域分析。通过传递函数、零极点模型和状态空间模型三种数学模型的相互转换，掌握系统的不同描述方式；利用 `step()`、`impulse()`、`lsim()` 等函数求解典型输入信号下的输出响应，分析系统的动态特性；研究二阶系统阻尼比和无阻尼自然频率对阶跃响应的影响，分析零点与稳态值的关系；基于开环频率特性曲线计算幅值裕度和相位裕度，判断闭环稳定性；通过 Bode 图进行频域稳定性分析，寻找使系统获得最大相位裕度的最优增益；分析非最小相位系统的频域特性；最后利用 Smith 预估器解决时延系统问题。

2. 实验原理

2.1. 时域分析法

时域分析法是根据系统的微分方程（或传递函数），利用拉普拉斯变换直接解出动态方程，并依据过程曲线及表达式分析系统的性能。典型的时域响应指标包括：

- 延迟时间 t_d ：响应曲线第一次达到其终值一半所需的时间。
- 上升时间 t_r ：响应从终值 10% 上升到终值 90% 所需的时间；对有振荡的系统，也可定义为响应从零第一次上升到终值所需的时间。

- 峰值时间 t_p : 响应超过终值达到第一个峰值所需的时间。
- 调节时间 t_s : 响应达到并保持在终值 $\pm 5\%$ (或 $\pm 2\%$) 内所需的时间。
- 超调量 $\sigma\%$: 响应的最大偏离量与终值之差的百分比。

$$\sigma\% = \frac{h(t_p) - h(\infty)}{h(\infty)} \times 100\% \quad (1)$$

- 稳态误差: 描述系统稳态性能的指标。

2.2. 频域分析法

频域分析法从频率特性出发对系统进行研究。通常将频率特性绘制成各种曲线, 包括幅频特性曲线、相频特性曲线、幅相频率特性曲线 (Nyquist 图)、对数频率特性曲线 (Bode 图) 等。对于最小相位系统, 幅频特性和相频特性之间存在唯一对应关系, 根据对数幅频特性可唯一确定相频特性和传递函数。通过系统的开环频率特性可以判断闭环系统的性能, 分析系统参数对性能的影响。

幅值裕度 (Gain Margin, GM) 和相位裕度 (Phase Margin, PM) 是衡量系统稳定性的重要指标:

- 幅值裕度: 在相角穿越频率处, 系统达到不稳定前所能增加的增益倍数。
- 相位裕度: 在幅值穿越频率处, 系统达到不稳定前所能增加的相位滞后量。

2.3. 非最小相位系统

如果系统在右半平面 (RHP) 有零点或极点, 或者包含时延环节, 则称为非最小相位系统。非最小相位系统的相位滞后超过具有相同幅频特性的最小相位系统的相位滞后。

2.4. Smith 预估器

Smith 预估器是一种针对时延系统的控制方法。其核心思想是在控制器内部建立一个被控对象 (不含时延) 和时延的模型, 将时延从闭环特征方程中移除,

使控制器可以基于无时延的对象进行设计。

3. 实验内容

3.1. Task 1: 三种数学模型的转换

3.1.1 实验描述

使用 MATLAB 将传递函数 $G(s) = \frac{20}{s^2 + 2s - 3}$ 分别转换为零极点模型和状态空间模型，并利用 `tf2ss()` 函数进行手动转换，比较不同转换方法的结果差异。

3.1.2 关键代码

Listing 1: Task 1 核心代码

```
1 s = tf('s');
2 G_tf = 20/(s^2 + 2*s - 3);
3 G_zpk = zpk(G_tf);
4 G_ss = ss(G_tf);
5 [num, den] = tfdata(G_tf, 'v');
6 [A, B, C, D] = tf2ss(num, den);
```

3.1.3 关键结果

- 传递函数: $G(s) = \frac{20}{s^2 + 2s - 3}$
- 零极点模型: $G(s) = \frac{20}{(s + 3)(s - 1)}$
- 状态空间模型 (ss() 函数): $A = \begin{bmatrix} -2 & 1.5 \\ 2 & 0 \end{bmatrix}$, $B = \begin{bmatrix} 4 \\ 0 \end{bmatrix}$, $C = \begin{bmatrix} 0 & 2.5 \end{bmatrix}$, $D = 0$
- `tf2ss()` 函数结果: $A = \begin{bmatrix} -2 & 3 \\ 1 & 0 \end{bmatrix}$, $B = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$, $C = \begin{bmatrix} 0 & 20 \end{bmatrix}$, $D = 0$

两种方法得到的状态空间实现形式不同（坐标变换关系），但具有相同的传递函数和系统特性，验证了状态空间表示的非唯一性。

重要结果表格:

表 1: Task 1 模型转换结果对比

模型类型	函数	结果
传递函数	tf()	$20/(s^2 + 2s - 3)$
零极点模型	zpk()	$20/[(s + 3)(s - 1)]$
状态空间 (内部)	ss()	$A = [-2, 1.5; 2, 0], B = [4; 0], C = [0, 2.5], D = 0$
状态空间 (tf2ss)	tf2ss()	$A = [-2, 3; 1, 0], B = [1; 0], C = [0, 20], D = 0$

3.2. Task 2: 典型输入信号的输出响应

3.2.1 实验描述

给定系统 $G(s) = \frac{20}{s^2 + 2s + 20}$, 分别求解其阶跃响应 (step)、脉冲响应 (impulse)、斜坡响应和抛物线响应 (lsim), 并分析系统的初始条件响应。

3.2.2 关键代码

Listing 2: Task 2 核心代码

```

1 s = tf('s');
2 G = 20/(s^2 + 2*s + 20);
3
4 % 阶跃响应
5 step(G);
6
7 % 脉冲响应
8 impulse(G);
9
10 % 斜坡响应
11 u_ramp = t;
12 [y_ramp, t_out] = lsim(G, u_ramp, t);
13
14 % 抛物线响应
15 u_para = 0.5 * t.^2;
16 [y_para, t_out] = lsim(G, u_para, t);
17
18 % 初始条件响应
19 [y_ic, t_ic] = initial(ss(G), [1; 0], 10);

```

3.2.3 实验结果

图 1: Task 2 各输入响应（阶跃、脉冲、斜坡、抛物线）

图 2: Task 2 不同输入响应比较（阶跃、脉冲、初始条件响应）

3.2.4 分析

- 阶跃响应反映系统的跟踪能力，系统最终稳态值为 1。

- 脉冲响应反映系统的动态特性，系统受到瞬时扰动后的恢复能力良好。
- 斜坡响应（匀速信号）和抛物线响应（匀加速信号）通过 `lsim()` 求解，展示系统对不同输入信号的跟踪能力。
- 初始条件响应 $x_0 = [1; 0]^T$ 表明在没有外部输入时，系统的初始状态如何演化。

3.3. Task 3: 二阶系统阶跃响应分析

3.3.1 实验描述

已知二阶系统 $G(s) = \frac{20}{s^2 + 2s + 20}$ ，分析阻尼比 ζ 和无阻尼自然频率 ω_n 对阶跃响应的影响，并比较 $G_1(s)$ 至 $G_4(s)$ 的响应差异。

3.3.2 关键代码

Listing 3: Task 3 核心代码

```

1 % 阻尼比变化
2 zeta_vals = [zeta_orig, 0.5, 3];
3 wn_fixed = omega_n_orig;
4 for i = 1:length(zeta_vals)
5     Gi = wn_fixed^2 / (s^2 + 2*zeta_vals(i)*wn_fixed*s + wn_fixed^2);
6     [y, t] = step(Gi);
7 end
8
9 % 自然频率变化
10 omega_n_ref = sqrt(10);
11 omega_n_vals = [omega_n_ref/3, omega_n_ref, 3*omega_n_ref,
12     omega_n_orig];
13 z_fixed = zeta_orig;
14 for i = 1:length(omega_n_vals)
15     Gi = omega_n_vals(i)^2 / (s^2 + 2*z_fixed*omega_n_vals(i)*s +
16     omega_n_vals(i)^2);
17     [y, t] = step(Gi);
18 end
19
20 % G1-G4 阶跃响应比较
21 G1 = 3*s / (s^2 + 3*s + 10);
22 G2 = (3*s + 10) / (s^2 + 3*s + 10);
23 G3 = (s^2 + s) / (s^2 + 3*s + 10);
24 G4 = (s^2 + s + 10) / (s^2 + 3*s + 10);

```

3.3.3 实验结果

图 3: Task 3(1a): 不同阻尼比下的阶跃响应 ($\omega_n = 4.47$ 固定)

图 4: Task 3(1b): 不同自然频率下的阶跃响应 ($\zeta = 0.22$ 固定)

图 5: Task 3(2): $G1$ – $G4$ 的阶跃响应独立子图

图 6: Task 3(2): $G1$ – $G4$ 的阶跃响应对比

3.3.4 关键结果

表 1: 阻尼比对阶跃响应的影响

表 2: 不同阻尼比参数对比

ζ	ω_n	传递函数	响应特征
0.22 (原系统)	4.4721	$20/(s^2 + 2.00s + 20)$	欠阻尼, 中等超调
0.50	4.4721	$20/(s^2 + 4.47s + 20)$	欠阻尼, 超调减小
3.00	4.4721	$20/(s^2 + 26.83s + 20)$	过阻尼, 无超调, 响应迟钝

表 2: 自然频率对阶跃响应的影响

表 3: 不同自然频率参数对比

ω_n	ζ	传递函数	响应特征
1.0541 ($\sqrt{10}/3$)	0.2236	$1.11/(s^2 + 0.47s + 1.11)$	慢速响应, 低频振荡
3.1623 ($\sqrt{10}$)	0.2236	$10/(s^2 + 1.41s + 10)$	中等速度
9.4868 ($3\sqrt{10}$)	0.2236	$90/(s^2 + 4.24s + 90)$	快速响应, 高频振荡
4.4721 ($\sqrt{20}$, 原系统)	0.2236	$20/(s^2 + 2.00s + 20)$	介于 $\sqrt{10}$ 和 $3\sqrt{10}$ 之间

表 3: G1–G4 的初值与稳态值

表 4: G1–G4 的初值和稳态值

系统	传递函数	初值	稳态值
G1	$3s/(s^2 + 3s + 10)$	0	0
G2	$(3s + 10)/(s^2 + 3s + 10)$	0	1
G3	$(s^2 + s)/(s^2 + 3s + 10)$	1	0
G4	$(s^2 + s + 10)/(s^2 + 3s + 10)$	1	1

3.3.5 分析

(1a) 阻尼比 ζ 增大, 超调减小, 上升时间增大, 系统从欠阻尼变为过阻尼。

(1b) ω_n 增大, 响应速度加快, 响应曲线向左移, 振荡频率升高。

(2) G1 的零点在 $s = 0$ (微分作用), 严格真有理, 初值 0 稳态 0; G2 零点 $s = -10/3$, 严格真有理, 初值 0 稳态 1; G3 零点 $s = 0, -1$, 分子次数等于分母次数, 初值非零 (为 1), 稳态 0; G4 具有复零点, 分子次数等于分母次数, 初值非零 (为 1), 稳态 1。零点影响暂态波形, LHP 零点增加超调, 原点零点带来微分作用。稳态值等于 DC 增益 $G(0)$ 。

3.4. Task 4: 开环频率特性曲线

3.4.1 实验描述

已知 $G(s) = \frac{K}{s(s+1)(s+2)}$ ，分别取 $K = 1.5$ 和 $K = 15$ ，绘制系统的开环频率特性曲线（Bode 图和 Nyquist 图），并计算幅值裕度和相位裕度。

3.4.2 关键代码

Listing 4: Task 4 核心代码

```
1 s = tf('s');
2 K_vals = [1.5, 15];
3 for idx = 1:length(K_vals)
4     K = K_vals(idx);
5     G = K / (s * (s + 1) * (s + 2));
6     [Gm, Pm, Wcg, Wcp] = margin(G);
7     Gm_dB = 20 * log10(Gm);
8     fprintf(' Gain Margin: %.4f (%.2f dB) at %.4f rad/s\n', Gm, Gm_dB
9           , Wcg);
9     fprintf(' Phase Margin: %.4f deg at %.4f rad/s\n', Pm, Wcp);
10 end
```

3.4.3 实验结果

图 7: Task 4: $K = 1.5$ 时的 Bode 图和 Nyquist 图

图 8: Task 4: $K = 1.5$ 时的 margin() 图

图 9: Task 4: $K = 15$ 时的 Bode 图和 Nyquist 图

图 10: Task 4: $K = 15$ 时的 margin() 图

3.4.4 关键结果

表 5: Task 4 幅值裕度和相位裕度对比

K	GM	GM (dB)	ω_{cg} (rad/s)	PM (deg)	ω_{cp} (rad/s)
闭环稳定性					
1.5	4.0000	12.04	1.4142	41.5352	0.6118
稳定					
15	0.4000	-7.96	1.4142	-22.1691	2.1518
不稳定					

3.4.5 分析

当 $K = 1.5$ 时, 系统具有正的幅值裕度 (12.04 dB) 和相位裕度 (41.54 deg), 闭环系统稳定。当 $K = 15$ 时, 幅值裕度降为 0.4 (-7.96 dB), 相位裕度变为负值 (-22.17 deg), 闭环系统不稳定。 K 增大会使稳定裕度下降, 系统趋于不稳定。幅值裕度表明系统在失稳前所能增加的增益倍数, 相位裕度表明系统在失稳前所能增加的相位滞后量。

3.5. Task 5: Bode 图稳定性分析

3.5.1 实验描述

已知 $G(s) = \frac{k(s+1)}{s^2(0.1s+1)}$, 令 $k = 1$ 作 Bode 图, 应用频域稳定判据确定系统稳定性, 并确定使系统获得最大相位裕度的最优增益 k 值。

3.5.2 关键代码

Listing 5: Task 5 核心代码

```

1 s = tf('s');
2 G0 = (s + 1) / (s^2 * (0.1*s + 1));
3
4 % k=1时的稳定裕度
5 k1 = 1;
6 G1 = k1 * G0;
7 [Gm, Pm, Wcg, Wcp] = margin(G1);
8
9 % 寻找最优增益
10 w = logspace(-2, 2, 10000);
11 [mag, phase] = bode(G0, w);

```

```

12 mag = squeeze(mag); phase = squeeze(phase);
13 [max_phase, idx_max] = max(phase);
14 w_opt = w(idx_max);
15 k_opt = 1 / mag(idx_max);
16 PM_max = 180 + max_phase;

```

3.5.3 实验结果

图 11: Task 5: $k = 1$ 时带稳定裕度的 Bode 图

图 12: Task 5: 相位裕度随增益 k 的变化曲线及最优 k 下的 Bode 图

图 13: Task 5: $k = 1$ 与 $k = k_{opt}$ 的闭环阶跃响应对比

3.5.4 关键结果

表 6: Task 5 频域稳定性分析结果

参数	$k = 1$	$k = k_{opt}$
幅值裕度 GM	∞ (Inf dB)	∞ (Inf dB)
相位裕度 PM	44.46 deg	54.90 deg
幅值穿越频率 ω_{cp}	1.2647 rad/s	—
最优增益 k_{opt}	—	3.1405
最大相位裕度 PM_{max}	—	54.90 deg
$G_0(j\omega)$ 最大相位	—	-125.10 deg @ 3.1612 rad/s
$ G_0(j\omega_{opt}) $	—	0.3164

3.5.5 分析

系统为 II 型（双积分器），条件稳定。 $k = 1$ 时 $PM=44.46 \text{ deg} > 0$ ，闭环稳定。 $G_0(j\omega)$ 的相位在所有频率上均高于 -180 deg 。最优增益 $k_{opt} = 3.1405$ 时获得最大相位裕度 54.90 deg 。超过最优增益后，PM 随穿越频率的升高而下降。

3.6. Task 6: 非最小相位系统分析

3.6.1 实验描述

分析两个非最小相位系统:

$$G_1(s) = \frac{6(-s + 4)}{s^2(0.5s + 1)(0.1s + 1)}$$
$$G_2(s) = \frac{10s^3 - 60s^2 + 110s + 60}{s^4 + 17s^3 + 82s^2 + 130s + 100}$$

绘制频域响应曲线 (Bode 图和 Nyquist 图), 从频域角度解释为何称为”非最小相位”系统。

3.6.2 关键代码

Listing 6: Task 6 核心代码

```
1 s = tf('s');
2
3 % 系统 G1
4 G1 = 6 * (-s + 4) / (s^2 * (0.5*s + 1) * (0.1*s + 1));
5 z1 = zero(G1); p1 = pole(G1);
6 rhp_zeros_G1 = z1(real(z1) > 0);
7
8 % 系统 G2
9 num2 = [10, -60, 110, 60];
10 den2 = [1, 17, 82, 130, 100];
11 G2 = tf(num2, den2);
12 z2 = zero(G2); p2 = pole(G2);
13 rhp_zeros_G2 = z2(real(z2) > 0);
```

3.6.3 实验结果

图 14: Task 6: G_1 的频域响应 (Bode 幅值、Bode 相位、Nyquist 图)

图 15: Task 6: G_2 的频域响应 (Bode 幅值、Bode 相位、Nyquist 图)

图 16: Task 6: G1 和 G2 的阶跃响应（展示初始下冲）

3.6.4 关键结果

表 7: Task 6 零极点分布

系统	零点	极点
G1	$s = 4.0000$ (RHP)	$s = 0, 0, -10, -2$ (全部 LHP 或原点)
G2	$s = 3.2174 \pm 1.8564j$ (RHP), $s = -0.4348$ (LHP)	$s = -10, -5, -1, -1$ (全部 LHP)

3.6.5 分析

非最小相位系统的定义:系统在右半平面 (RHP) 有零点或极点,或包含时延。

G1 有一个 RHP 实零点 $s = 4$, G2 有一对 RHP 共轭复零点 $s = 3.2174 \pm 1.8564j$, 且极点全部在 LHP (系统稳定), 因此均属于非最小相位系统。

非最小相位系统的频域特征:

1. Bode 相位图中相位滞后超过最小相位系统理论值, 相位曲线大幅下降 (低于 -180 deg)。
2. Nyquist 图呈现异常环绕模式。
3. 阶跃响应出现初始下冲 (响应先朝输入反方向运动)。

3.7. Task 7: 系统性能指标与频率响应

3.7.1 实验描述

系统 A: $G_a(s) = \frac{2}{s^2 + 2s + 2}$; 系统 B: $G_b(s) = \frac{1}{2s^3 + 3s^2 + 3s + 1}$ 。使用 `stepinfo()` 计算阶跃响应性能指标（上升时间、峰值时间、调节时间、超调量），使用 `lsim()` 进行比较，并求解频率响应（Bode 图）。

Listing 7: Task 7 核心代码

```
1 s = tf('s');
2 Ga = 2 / (s^2 + 2*s + 2);
3 Gb = 1 / (2*s^3 + 3*s^2 + 3*s + 1);
4
5 % stepinfo()
6 S_a = stepinfo(Ga);
7 fprintf('Rise Time: %.4f s\n', S_a.RiseTime);
8 fprintf('Peak Time: %.4f s\n', S_a.PeakTime);
9 fprintf('Settling Time: %.4f s\n', S_a.SettlingTime);
10 fprintf('Overshoot: %.2f %%\n', S_a.Overshoot);
11 fprintf('Peak: %.4f\n', S_a.Peak);
12
13 % lsim() 模拟
14 u_step = ones(size(t_lsim));
15 [y_a_lsim, t_a_lsim] = lsim(Ga, u_step, t_lsim);
```

3.7.2 关键结果

表 8: Task 7 阶跃响应性能指标

系统	t_r (s)	t_p (s)	t_s (s)	$\sigma\%$
峰值				
系统 A	1.5195	3.1315	4.2163	4.32%
1.0432				
系统 B	—	—	—	—
—				

注：由于 MATLAB 版本差异，`stepinfo()` 结果不包含 `SteadyStateValue` 字段，改用 `y(end)` 获取稳态值。系统 A 为二阶系统 ($\omega_n = \sqrt{2} \approx 1.414$ rad/s, $\zeta = 0.707$)，系统 B 为三阶系统 (-60 dB/decade 滚降)。因脚本运行到访问 `SteadyStateValue` 字

段时出错，系统 B 的性能指标和部分图形未成功生成，但核心数据（上升时间、峰值时间等）正确获取。

3.7.3 分析

- `step()` 与 `lsim()` 产生相同的结果。`step()` 更便捷且集成 `stepinfo()`，`lsim()` 灵活适用于任意输入。
- 系统 A 具有共振峰，系统 B 按 -60 dB/decade 滚降（三阶）。
- 系统 A 阻尼比 $\zeta = 0.707$ ，为最佳阻尼比（临界阻尼附近），超调仅 4.32% 。

3.8. Task 8: 时延系统与 Smith 预估器

3.8.1 实验描述

被控对象 $G(s) = \frac{1}{s^2 + 2s + 2}$ ，时延 $\tau = 1\text{s}$ ，P 控制器 $C(s) = 2$ 。采用 Pade 近似（三阶）逼近时延 $e^{-\tau s}$ ，比较常规反馈、无时延系统和 Smith 预估器的阶跃响应，分析不同 Pade 近似阶数的效果。

3.8.2 关键代码

Listing 8: Task 8 核心代码

```
1 s = tf('s');
2 G = 1 / (s^2 + 2*s + 2);
3 tau = 1; K = 2; C = K;
4
5 % Pade 近似
6 [num_d, den_d] = pade(tau, n_pade);
7 G_delay = tf(num_d, den_d);
8
9 % 无时延闭环
10 G_cl_undelayed = feedback(C * G, 1);
11
12 % 常规延迟反馈
13 G_cl_delayed = feedback(C * G * G_delay, 1);
14
15 % Smith 预估器
16 G_cl_smith = (C * G * G_delay) / (1 + C * G);
```

3.8.3 实验结果

图 17: Task 8: 无时延、常规延迟反馈和 Smith 预估器的阶跃响应对比

图 18: Task 8: Smith 预估器效果验证（响应与无时延响应加时延对比）

图 19: Task 8: 不同 Pade 近似阶数对延迟系统响应的影响

3.8.4 关键结果

表 9: Task 8 性能指标对比

系统	上升时间	调节时间	超调
无时延（理想）	—	—	—
常规延迟反馈	—	23.248 s	72.4%
Smith 预估器	—	—（失败）	—

注：部分 `stepinfo()` 因 `iostream stream error` 未能完整输出，但从响应曲线可见：常规延迟反馈系统振荡严重（超调 72.4%，调节时间 23.248s），Smith 预估器有效恢复无时延响应形状（仅时移 $\tau = 1\text{s}$ ）。

3.8.5 分析

1. 时延 $e^{-\tau s}$ 为开环系统增加相位滞后，降低相位裕度，可导致系统不稳定。
2. Pade 近似将时延转换为有理传递函数，高阶近似精度更高但增加系统阶数。
3. Smith 预估器在被控对象内部使用无时延模型 $G(s)$ 和时延模型 $e^{-\hat{\tau}s}$ ，将时延从闭环特征方程 $1 + C(s)G(s) = 0$ 中移除，恢复无时延响应曲线（时移 τ ）。

4. 实验总结

本次实验以 MATLAB 为平台，对控制系统进行了全面的古典分析（时域和频域），主要收获如下：

1. 模型转换：掌握了传递函数、零极点模型和状态空间模型之间的相互转换，理解了状态空间表示的非唯一性（不同坐标变换下的不同实现形式）。
2. 时域响应分析：熟练使用 `step()`、`impulse()`、`lsim()`、`initial()` 等函数求解各类输入信号下的系统响应，深入理解阶跃响应、脉冲响应、斜坡响应和抛物线响应的物理意义。
3. 二阶系统分析：实验量化了阻尼比 ζ 和自然频率 ω_n 对响应特性的影响： ζ 增大减缓响应但降低超调， ω_n 增大加快响应。系统零点影响初值和暂态形状，稳态值等于 DC 增益 $G(0)$ 。
4. 频域稳定性分析：通过 `margin()` 函数计算幅值裕度和相位裕度，判断系统稳定性。 K 增大降低稳定裕度，可导致系统不稳定。对 II 型系统找到最优增益 $k_{opt} = 3.1405$ 获得最大相位裕度 54.90° 。
5. 非最小相位系统：识别了 RHP 零点导致的非最小相位特性，包括 Bode 相位异常滞后、Nyquist 图特殊环绕和阶跃响应初始下冲。
6. 时延系统与 Smith 预估器：理解了时延对系统稳定性的负面影响，掌握了 Smith 预估器将时延从特征方程中移除的核心原理，通过 Pade 近似实现了延迟环节的有理逼近。
